Pruning Landscape Trees: An Overview

Mike Kuhns, State Extension Forester

This fact sheet describes why, when, and how to prune branches from landscape trees. It describes where to make pruning cuts to avoid stubs and flush-cuts, and describes why wound dressings

What Is Pruning?

Pruning is the purposeful removal of plant parts. Its use is preferred to less precise terms like *trimming*. This fact sheet deals mainly with pruning of branches on ornamental trees. It does not cover pruning of fruit trees for fruit production, shearing or other intensive crown shaping practices, or root pruning.

Why Prune?

Reasons for pruning landscape trees generally fit into three closely-related categories: *health*, *hazard*, and *form*. Step back and reconsider if you find yourself pruning off healthy, non-hazardous branches on a tree with good form.

Health — Pruning for tree health includes removal of insect or disease infested branches, broken or dead branches, crowded branches, and branches or portions of trunks with included bark. Pruning to “open-up” a tree’s crown to encourage light penetration or air movement generally is not needed.

Hazard — Pruning to reduce hazard to people or property includes removal of dead and decaying branches; branches that interfere with sight lines or travel along streets, driveways, or sidewalks; branches that rub against structures; thorny or spiny branches that might cause injury, and pruning for utility line clearance. Healthy,

strong, properly attached branches that overhang a building do not usually pose an unreasonable safety risk and do not necessarily need to be removed.

Form — Pruning for tree form or shape involves removal of certain branches and leaving others to direct growth toward and away from certain areas. Pollarding, crown raising, and topiary all are examples of pruning for form.

When to Prune

Time of Year — Pruning can be done at any time of year with special care and knowledge, but certain times are better than others. Pruning is best done in winter or early spring before buds swell when tree energy reserves are high and the tree is dormant. Though certain trees, such as birches, maples, and walnuts, may exude sap or “bleed” when pruned at this time of year, this is not a problem and stops within a few days. During the spring growth period bark is tender and easily damaged and pruning must be done very carefully. In fall pruning wounds may be more easily infected with decay microorganisms. Though summer pruning can be done, considerable dieback may occur at the edges of summer pruning wounds, possibly due to drying of the living tissues at wound edges. Quickly wrapping such wounds with white plastic sheeting can reduce this dieback (see page 4).

Time of Life — At planting time only prune branches that are dead, broken, or that have insect or disease problems. Otherwise, prune early in a branch or tree’s life to avoid pruning large branches or letting serious problems develop. For maintenance pruning on established trees try to prune branches before they exceed 2 inches in diameter.

Pruning Severity

Avoid pruning off more than 20 to 25% of a tree's leaf area in any year. Pruning stresses trees because pruning wound repair requires energy from food while pruning removes leaves that make food and wood that stores food. Younger and more vigorous trees can stand heavier pruning than mature or stressed trees. If heavy pruning is unavoidable, remove branches over two or more years to reduce stress.

Pruning Tools

Sharp, well-maintained tools make cleaner cuts and are safer than dull tools. Use shear-type hand pruners for small twigs (sometimes called bypass pruners; anvil-type pruners cause slightly more injury than shear-type), loppers for small branches, and pruning saws for branches up to 3 or 4 inches in diameter. Good pruning saws have thin curved blades and teeth that are angled back to cut mainly as you pull rather than push. Chainsaws should only be used for large branch removal. Bow saws are not suitable for pruning since their blade wanders and the handle gets in the way. Sterilization of tool blades between cuts (with alcohol or bleach) often is recommended to avoid spreading disease, but researchers have shown that most quick sterilization techniques are not effective.

Pruning Techniques

Safety — Removing large branches or cutting down entire trees is dangerous. Call in an insured, well-trained professional arborist (preferably certified by the International Society of Arboriculture) if you are unsure of your abilities or if climbing is involved. Pruning near utility lines should only be done by certified line clearance professionals — call your electric company.

Where to Cut: Natural Target Pruning — Good pruning involves removing as much of the branch as possible without leaving a stub or flush cutting. Good pruning cuts are called *natural target cuts* by arborists, who use two targets on the tree to show them where to make the cut. These targets are the *branch bark ridge* (BBR) and the *branch collar*. The BBR is an area of excess bark that accumulates where two branches meet. It extends down the branch or trunk on either side of the branch crotch. The branch collar is (typically) a swollen, wrinkled area at the branch base where branch and trunk (or branch and branch) tissues come together.

Natural target pruning of dead and live branches; broadleaves (top) and conifers (bottom). Final cuts should be from A to B.

A natural target cut leaves the BBR and branch collar on the tree without leaving a stub. Such a cut passes just outside the BBR on top and usually slants out and down, leaving a bump but no stub (from A to B on diagram). Sometimes the swollen branch collar extends all the way around the branch base and the resulting cut is more vertical. Though the “targets” usually are easy to see on most broadleaved trees, some trees like sycamore constantly lose bark and don't accumulate a BBR. Conifers also may not accumulate a typical BBR. In both cases, just cut outside any swollen or wrinkled branch collar.

Wound Closure — Natural target cuts start to seal over quickly as *woundwood*, sometimes called *callus*, forms at the wound edges (callus forms first and becomes woundwood as it matures and becomes woody).

Woundwood usually forms in a continuous ring around a natural target cut, eventually sealing over the wound as it grows together. Gaps in the woundwood at the top and/or bottom indicate flush-cuts, cuts that were made too close to the stem (see below). Though such wounds may eventually seal, they have a greater chance for dieback, decay, and crack formation than natural target cuts. The term “seal,” rather than “heal,” is used to describe tree wound closure, since the wound still exists inside the tree even after it no longer shows on the outside.

Woundwood patterns around a natural target cut (A-B), versus cuts made too close at the top (C-B), bottom (A-D), or top and bottom (C-D).

Pruning Dead Branches — Shortly after a branch dies a swollen ring of woundwood starts to form around its base. A branch protection zone also forms in the wood at the branch base. This zone contains chemicals that help the tree resist microbial attack. Cut off dead branches just outside the live woundwood without leaving a stub (see broadleaved diagram on page 2). Promptly remove large dead branches since they pose significant hazards.

Pruning Large Branches and Narrow Angles — Remove large branches with a three step cut: an undercut one-third of the way up through the branch one or two feet out from the trunk (to prevent bark stripping), a top cut directly into or slightly outside of the undercut to remove most of the branch weight, and a final natural target cut that removes the stub. Final cuts can be made from the bottom up to the crotch (B to A in the previous diagrams) if the branch angle is tight and tools won't fit in the crotch.

Pruning Leaders or Co-dominant Stems — Pruning to remove a leader or main stem sometimes is called crown reduction. A leader can be pruned off where another branch is attached if the remaining branch is healthy and

vigorous and at least 1/3 the diameter of the leader to be removed (so a 6" leader could be removed at a 2" branch). Also, no more than about one-quarter of the foliage should be removed from the branch that is being shortened. The final pruning cut should be on the other side of the BBR sloping out and down with the bottom of the cut straight across from the bottom of the BBR. As before, the BBR remains on the tree and no stub is formed. Co-dominant stems (stems nearly equal in size) are pruned similarly.

Natural target pruning of a leader. Final cut from A to B with B straight across from bottom of BBR (C). Remaining branch is healthy and at least 1/3 the diameter of leader being removed.

Included Bark — Sometimes the bark where two branches meet turns in instead of out, forming a seam of *included bark* inside the tree instead of a BBR. Areas of included bark often die and become decayed. These areas are naturally weaker than branch attachments with normal BBRs. Included bark is especially common on certain species or cultivars, like Bradford pear and littleleaf European linden, but can be found on any tree. It also is more common where branches attach to one another at a very narrow angle, but can occur with wide attachment angles. Avoid purchasing trees with included bark.

Don't prune off all branches with included bark (on some trees nothing would be left), but watch for signs of dieback or cracks extending down from the crotch below the bark seam. Remove a branch that has included bark by cutting from the open crotch down and out (or cut up to the crotch). This actually leaves a small stub on or in the tree, but cutting farther down may cause serious trunk wounds.

Wound Care

Wound Dressings — Pruning wounds and other tree wounds should be left open to the air, with no covering or dressing (see exception below). Though various paints, shellacs, and tar-like materials are available for treating wounds, none have been shown to slow or prevent decay or promote wound healing or sealing. In fact, research

has shown that such dressings can actually promote decay by keeping the wound protected and moist — perfect conditions for the growth of decay microorganisms.

An exception is the use of white polyethylene sheeting to wrap wounds made in summer when conditions are hot and dry. Recent research has shown that wrapping wounds with such sheeting (preferably within minutes of pruning) results in less dieback and better healing than with unwrapped wounds. Wrapping can be held on the tree with tape and can be removed in two or three weeks.

Scribing and Wound Shaping — In the past it has been thought that wounds needed to be shaped or scribed to promote healing. Researchers have found, however, that scribing simply makes wounds larger and is not needed. Wounds from natural target pruning usually heal well on their own. Always remove any loose bark or pieces of wood that stick out from a wound.

Topping

Trees should never be topped. Topping or rounding-over is the removal of branches without regard to where other branches attach, usually leaving stubs. Topping is done to gain clearance from an obstruction or to reduce a tree's height or crown spread. Sometimes cuts are made where a branch is attached, but the remaining branch is too small or weak to assume dominance. Quick regrowth, combined with decay in the stubs, leads to poor tree health and potential hazards. Unfortunately, there is no long-term way to keep a tree small and healthy if it is naturally large.

Topping (left) leaves many stubs that encourage decay and sprouting. Directional pruning (right) minimizes sprouting and decay using natural target pruning.

An Alternative to Topping: Directional Pruning — Directional pruning is the removal of branches with natural target cuts to guide growth away from certain locations. It is commonly used to keep branches out of utility lines without topping, but it is useful in many other circumstances. Just start at the tip of the branch to be removed and follow it back to where it meets another healthy branch that can remain on the tree and that is large enough to assume dominance (at least 1/3 the diameter of the branch to be removed). Remove unwanted branches with natural target cuts as described earlier.

For More Information

Contact the Utah Community Forest Council (UCFC), P.O. Box 961, Salt Lake City, UT 84110-0961, for a copy of the booklet *Utah Shade Tree Pruning Standards*, or for other community forestry information. Other pruning-related publications available through the UCFC include:
